- DFS (Depth First Search) :-

  It is solely based on recursion.

- In all the problems which involves recursion, keep following points in mind :

1. Identify the parameters

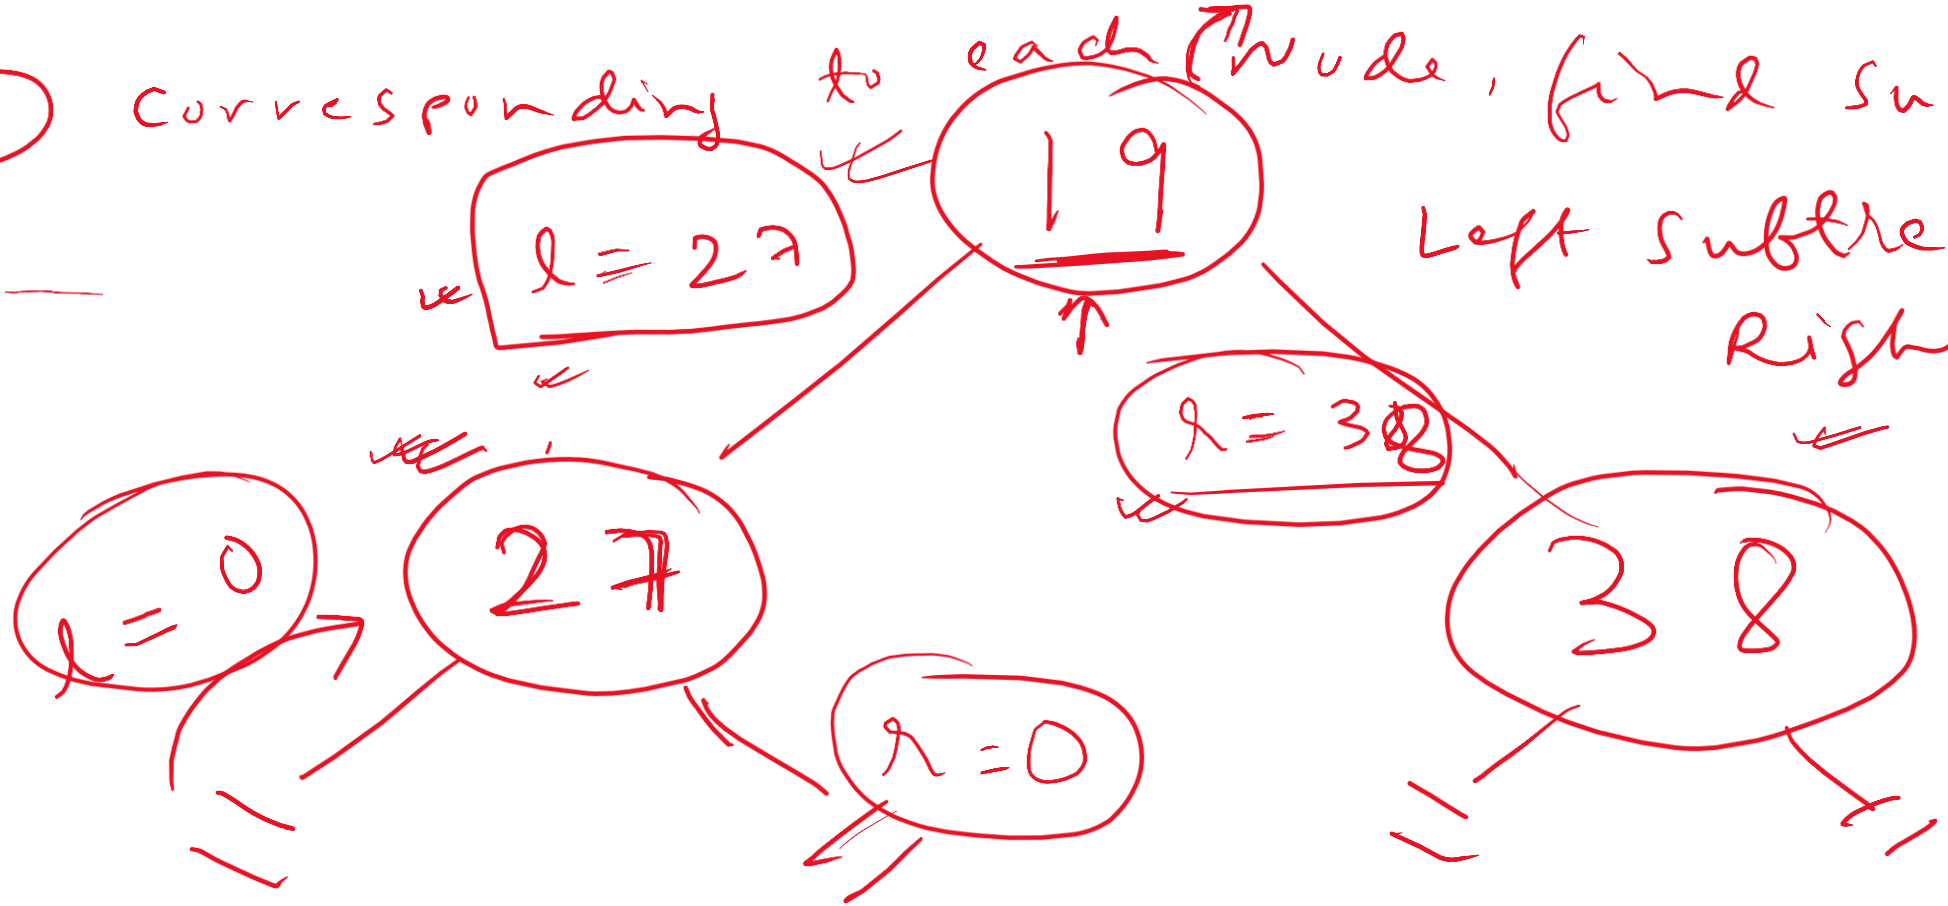
2. Think of Base Cond^n & return correct value.

3. Think of parametric change that you will need to make while making recursive f^n call.

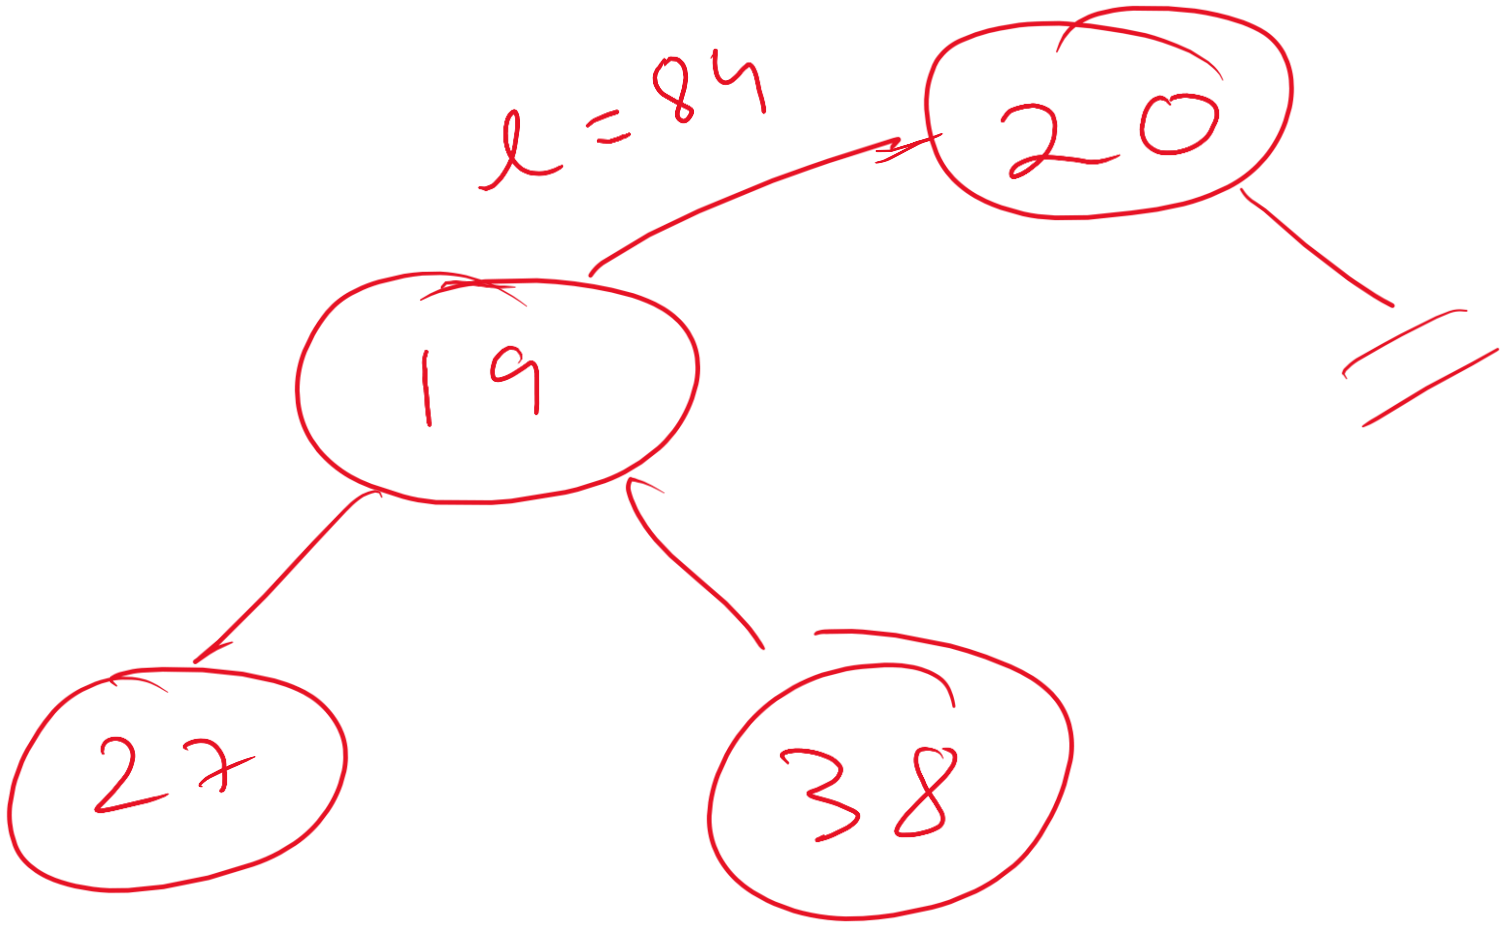
4. Think of a value that you will need to return in the end of function back to it's parent function call.

- Recursive f^n will be executed for each Node present in the Binary Tree.

(1) Corresponding to each Node, find sum of Left subtree & Right subtree



```
int fun( Node * root )
{
    if (root == null) return 0;
    if(root.left==null && root.right==null) return root.data;
    int l = fun( root.left ); int r = fun(r.right);
    return (l + r) + (root.data);
}
```



l = 84
20
19
27
38

- Get into habit of using Helper function where you can use more number of parameters based on the need of the problem.
